

CAMDEX *drives*

Precision Cam Indexing Drives

Indexing Solutions

Product Catalogue 2012

Company Profile

CAMDEX Machine Works Co., Ltd. is a foreign-invested enterprise, and the first in China to use CNC cam grinding machines to produce hi-speed, precision indexing drives. CAMDEX's strengths include effective management strategies, advanced technology and manufacturing processes, professional equipment, sophisticated product testing and quality assurance, and warm, thoughtful service.

Use CAMDEX index drives for:

Auto assembly machines and processing machines; printing machines, pad printing machines, screen printing machines and gold stamping machines; packing machines and vacuum forming machines; automatic testing machines, sorting machines and counting machines; food processing machines; filling machines; pharmaceutical machines, sealing and capping machines and bottle filling machines; Any application where precision and/or high speed indexing is required, choose CAMDEX.

Indexing Solutions.

PROPERTIES

Unique Mechanical Features

1. Simplicity and Reliability

A high precision mechanism consisting of only two main moving parts, is capable of providing various types of indexing motions.

2. Inherent Accuracy

During the index drive's dwell (stationary) period, the output shaft (or flange) is accurately fixed in position, eliminating the need for a locking device. CAMDEX standard models are manufactured with an accuracy tolerance of ± 30 seconds ($1/120^{\text{th}}$ of a degree). Higher accuracy is available upon request.

3. Motion Curves

For different applications:

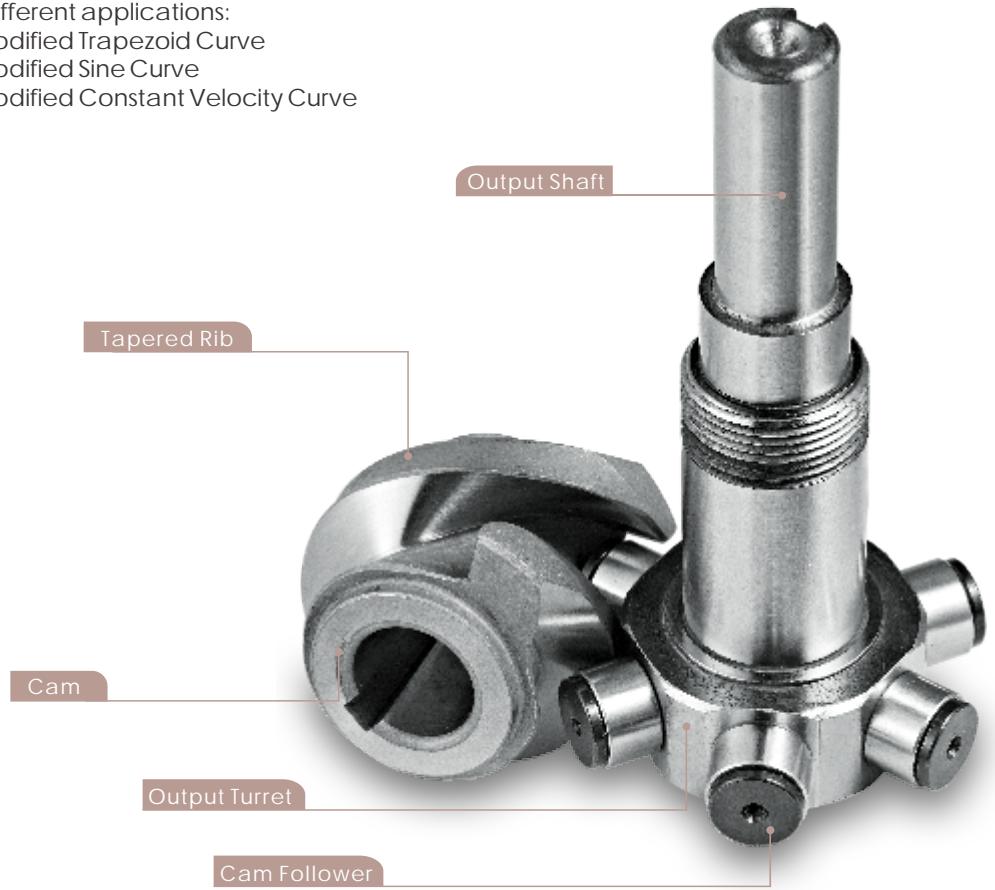

1. Modified Trapezoid Curve
2. Modified Sine Curve
3. Modified Constant Velocity Curve

4. Operation at High Speed

Precision cam followers and tapered ribs are preloaded to avoid gaps and thus capable of providing reliable hi-speed operation. The controlled acceleration and deceleration minimizes the impact caused by working loads.

5. Noise and vibration

CAMDEx index drives are designed to operate in any position, and customers will enjoy their quiet running and minimal vibration.

STRUCTURAL PRINCIPLE

Operating Principle and Structure

The structure of an index drive is quite simple. The cam, assembled with the input shaft, interfaces with the output turret. (Fig. 1) The cam followers are fixed in radials around the output turret and linearly contact the working surface of the tapered cam ribs.

The input shaft rotates, and the cam followers drive the output turret in accordance with the designed motion curve as they roll along the working surfaces of the cam. During the dwelling period, the cam followers do not drive the output turret, though they are still connecting it to the cam. They are locked in a steady and accurate dwell position by the cam. At all times, at least two followers are in continuous contact with the cam, ensuring input shaft rotation is evenly transmitted to the output shaft. This is what provides the smoothness of the indexing motion.

Terms and Definitions

1. Roller Gear Cam

A cam fluted into the surface of its barrel type solid body, and fixed to the input shaft.

2. Tapered Rib

The ribs which form the separate cam grooves. The polished sides of the ribs are the cam's working surfaces.

3. Cam Followers

A precision needle roller bearing, capable of working at high speed and heavy load.

4. Output Turret

The extension of the output shaft, driven by the roller gear cam and cam followers.

5. Number of Stops

The number of dwell periods per one revolution of the output shaft.

6. Index Angle

The rotational angle of the input shaft during an index period of the output turret.

7. Dwell Angle

The rotational angle of the input shaft during a dwell period; the sum of dwell angle and index angle is 360°.

8. Number of Rotations

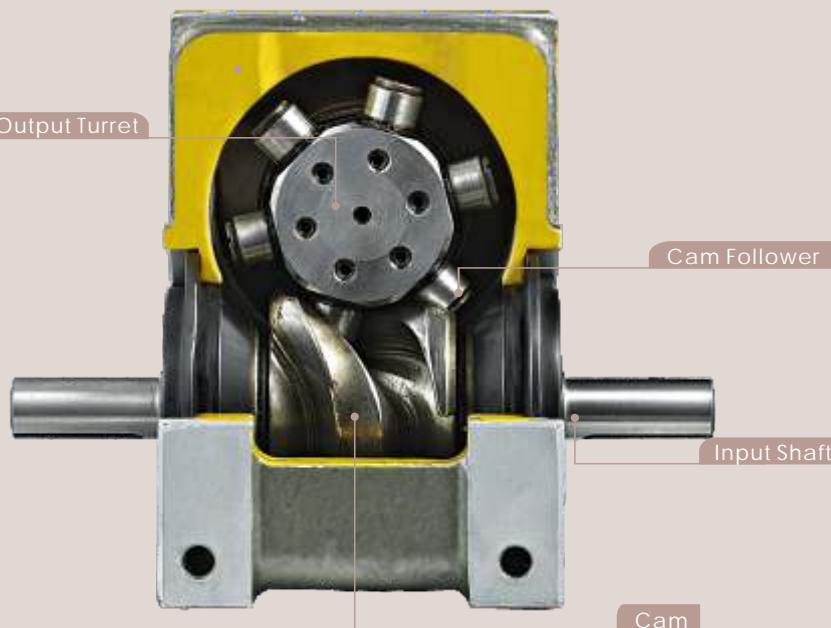

The number of input shaft rotations required to produce one full rotation of the output turret.

9. Steady State Torque

The maximum permissible external torque that may be exerted upon the output shaft by the machine during a dwell period.

10. Dynamic Torque

The maximum torque exerted to the output shaft during an index period.

STRUCTURAL PRINCIPLE

The motion diagram of an index drive is formed by connecting the start and end of all its motion curves. Indexing motions are designed to make the transition between curves and plateaus as smooth as possible to minimize vibration and noise. Material characteristics are taken into close consideration to produce maximum reliability, lifespan, load and speed ratings. Our indexers are designed to effect the best compromise between all factors. Custom designs can be requested to tilt the balance more towards one area.

The displacement curve shows the relationship between displacements of input shaft (indexing time and angle, etc.) and displacement of output shaft (fig.2). In the diagram, the horizontal axis represents the displacement of input shaft, 'θ' while the vertical axis stands for the displacement of output shaft with a given number of stops, 'S'.

Motion Curve

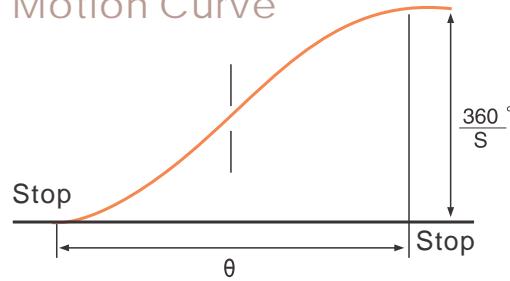

fig. 2

While selecting a cam curve, the values of the following properties must be considered:

- | | |
|----------------|--------------------------|
| V _m | The maximum velocity |
| A _m | The maximum acceleration |

When V_m is greater, there will be a greater force exerted to the cam when it suddenly stops. Therefore, generally a curve with less V_m should be selected, especially when the load is heavier. V_m is also closely related to the cam size. The size of a cam with a less V_m curve is smaller. Note that the value of V_m shall not be greater than 1.

When A_m is greater, the maximum load allowed is lighter. Therefore, a curve with less A_m should be selected in a hi-speed operation, where A_m shall not be less than 4.

STRUCTURAL PRINCIPLE

There are 3 CAMDEX standard indexing curves:

Modified Trapezoid Curve (MT)

For high speed and light load: fig.3

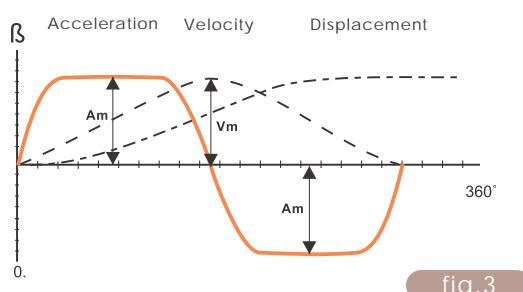

Modified Sine Curve (MS)

For moderate to high speed and moderate load: fig.4

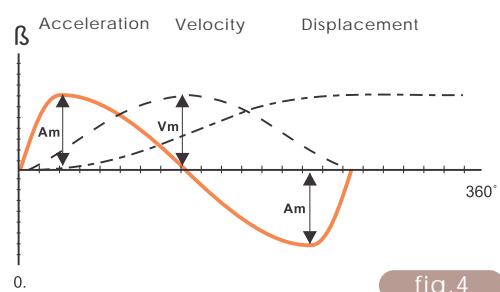

Modified Constant Velocity Curve (MCV50)

For low speed and heavy load: fig.5

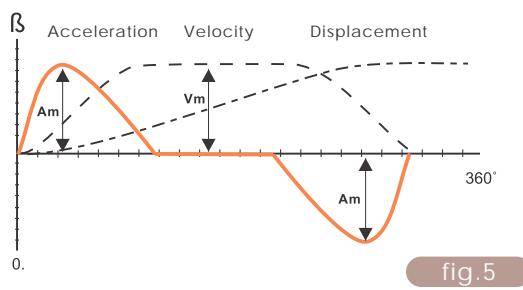

Modified Trapezoid Curve (MT)

Modified Sine Curve (MS)

Modified Constant Velocity Curve (MCV50)

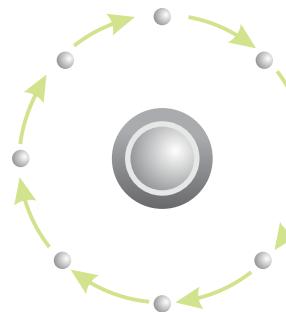

TYPES OF MOTION

Different Types of Drives Available

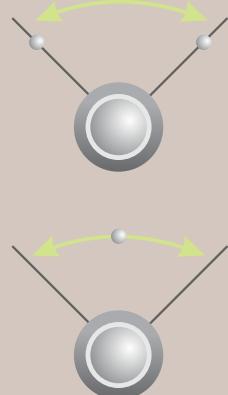

Indexing Drives:

- Convert continuous rotary input into a stop –move – stop motion.

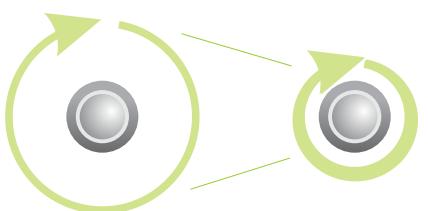

Oscillating Index Drives:

- Convert continuous rotary input into a left-right (back and forth) motion
- Can also produce a right-center-left-center motion.
- Are very stable and are suitable for high speed.

Roller Drives:

- Roller drive speed reducers are superior to worm gear and other types in several ways, such as zero backlash, significantly higher efficiency and required lower input torque.

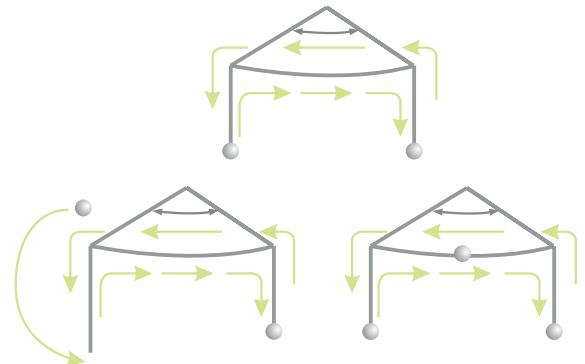

TYPES OF MOTION

Different Types of Drives Available

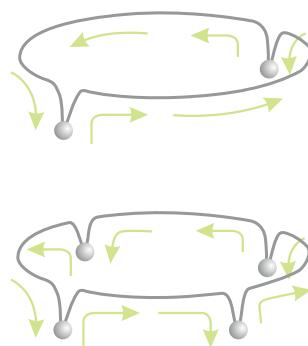

Oscillating and Conveying Drives:

- Oscillating and conveying drives operate similarly to standard oscillating drives, but incorporate a longitudinal reciprocating movement of the output as well. Different configurations of oscillation and reciprocity may be utilized.
- The output shaft oscillation can be set to stop at the middle point of the rotation. The rotation angle and lifting height can be set accordingly as well.

Indexing and Conveying Drives:

- Indexing and conveying drives operate similarly to standard indexing drives, but incorporate a longitudinal reciprocating movement of the output as well. The stop can be set at the middle point of the rotation. The rotation angle and lifting height can be set accordingly as well.

MODEL SELECTION AND CALCULATION

Symbols and Descriptions

a4	Dwell Coefficient	Lf	Lifespan Factor	Ti	Inertia Torque (kgf.m)

SERVICE EXAMPLES

Basic Examples

Auto Assembly Machine Series

This mechanism can be used in Auto Assembly Machines; Process Machines; Metal Process Machines; Step Drive Conveyors; FMS Relevant Equipment; Packing Machines; Food Machines; Sorting Machines; Medicine Machines; Printing Machines; Auto Detection Machines; Extrusion Feeding Devices, and indexing machines of other uses.

Examples using this device

Capacitor Production Machine

Capacitor Sorting Machine

Diode Production Machine

Automatic Balers

Lead Wire Welding and Stamping Machine

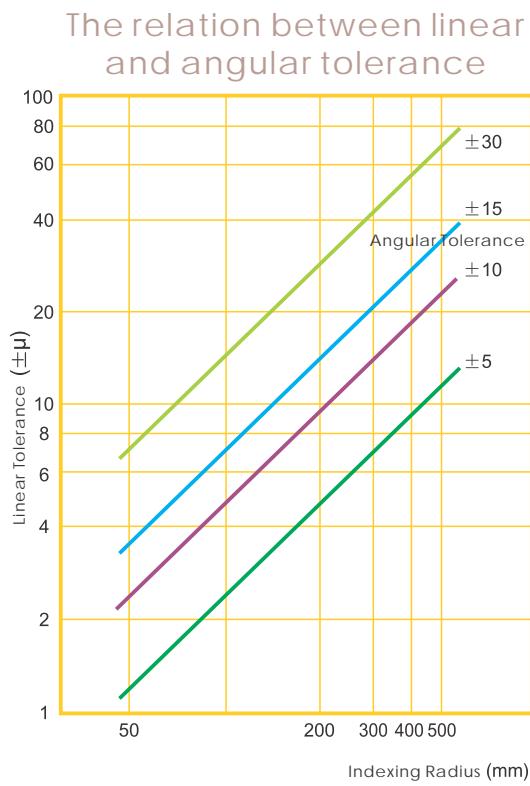

Automatic Filament Winding Machine

ACHIEVING PRECISION

Indexing Accuracy

Turn Table Size

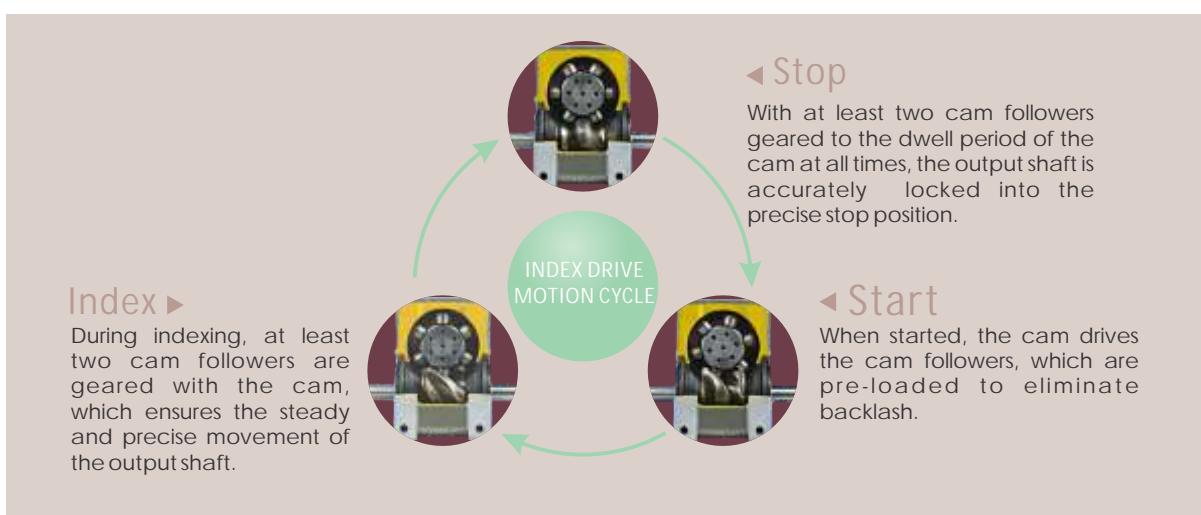

- To mount a turn table on the output shaft, the size of the turn table should be based on the load capacity of the output shaft torque allowed by Torque (Te).
- When high accuracy is required, Torque (Te) should be 2-3 times greater than the output shaft torque allowed; hence, the torque value of the output shaft should be reduced.
- The largest diameter of the turn table should be less than 5 times the distance of shaft centers. (fig. 6).

Indexing Accuracy

- The indexing accuracy is 30 seconds for standard level models, and 15 seconds for precision level models. Please note that the displacement will influence the accuracy when the turn table is mounted on the output shaft.

The largest diameter allowed of a standard turntable (mm)

Center distance	45	60	70	80	100	110	140	180	250
Largest diameter	225	300	350	400	500	550	700	900	1250

LUBRICATION AND MAINTENANCE

Lubrication and Maintenance

Proper lubrication and maintenance practices are extremely important to preserve the condition of, and maximize the lifespan of index drives. Proper lubrication is effective in reducing heat generation, preventing rust and reducing wear. Failure to observe recommended lubrication and maintenance practices will result in reduced lifespan, inaccuracy due to wear, and premature failure.

The selection of lubricant is also very important. For example, if the lubricant viscosity is too low, operational temperature rise will lower the dynamic viscosity. This will cause more heat, a resulting further degradation of dynamic viscosity and lead to oil film breakdown and rapid failure of the index drive.

Lubricating Oil Change

Improperly lubricated internals will lead to rapid wear. This in turn will adversely affect accuracy. Please make sure the index drive is no less than 1/3 full of oil, and observe the lubrication level indicator whenever installation orientation allows.

The first lubricating oil change must be performed between 500 to 1000 working hours (2-4 months) of the index drive. Regardless of the working hours, any lubricant will degrade over time, therefore regular lubricating oil changes are necessary.

Choice of Lubricants

- Lubrication is an important factor to maintain the accuracy and lifespan of index drives. When choosing lubricants, the conditions of use such as working environment and speed, etc. should be taken into full consideration.
- High quality gear oil should be used, with additives to strengthen oil film, and provide suitable anti corrosion properties also.
- Mixing lubricants from different manufacturers should be avoided.
- Oil viscosity varies due to different speed and device size. Please choose according to the following guidelines.
- Oil viscosity also changes as the environment temperature changes. The working temperature range of index drives is 0-40 celcius. Please refer to the following viscosity-temperature table and please contact us if your application exceeds this standard.

Note

- A. Lubricating Oil Change Cycle
 - The first oil change shall be performed in 500-1000 working hours (2-4 months)
 - Afterwards, change oil every 3000 working hours (6 months to 1 year)
- B. When changing oil, ensure the filling hole area is clean to avoid the entry of any contaminants.
- C. Temperature rise will increase the internal pressure, which may cause oil leakage. This should not be ignored. Regularly clean the filling hole and check ventilation hole, oil tubing and oil level, and add lubricant when necessary.

LUBRICATION AND MAINTENANCE

Lubrication and Maintenance

Lubricating Oil Viscosity, Table 4

Input Shaft Speed (rpm)	0~20	20~100	100~200	200~300	300~400	>400
Viscosity (cSt/40)	>680	680~460	460~320	320~220	220~150	150~68

- If input shaft speed is not steady, the viscosity can be determined with the speed of the longest-term operation or the geometric average of the maximum speed (N_{max}) and the minimum speed (N_{min}) $\sqrt{(N_{max}) \times (N_{min})}$
- Choose higher viscosity oil when the correspondent viscosity of the input shaft speed falls in between 2 viscosity ranges.

Lubricant Recommended, Table 5

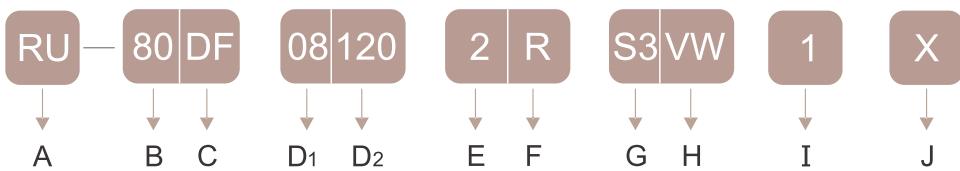

Viscosity (cSt/40)	Supplier		
	(Caltex)	(Shell)	(Mobil)
>600	Meropa680	Shell Omala Oil 680	Mobil Gear 636
680~460	Meropa460	Shell Omala Oil 460	Mobil Gear 633
460~320	Meropa320	Shell Omala Oil 320	Mobil Gear 632
320~220	Meropa220	Shell Omala Oil 220	Mobil Gear 630
220~150	Meropa150	Shell Omala Oil 150	Mobil Gear 629
150~68	Meropa68	Shell Omala Oil 68	Mobil Gear 626

Other Types Available

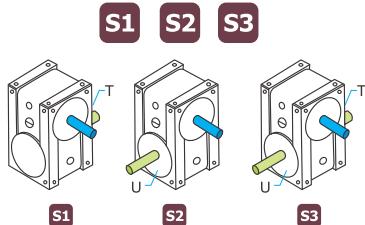

- H. Hollow flange type output shaft (applicable to 45D-250D)
- Hollow output shaft is usually for electric and pneumatic lines. Please specify the hole diameter and the application when placing orders.
- If not specified, the output shaft will be made solid.

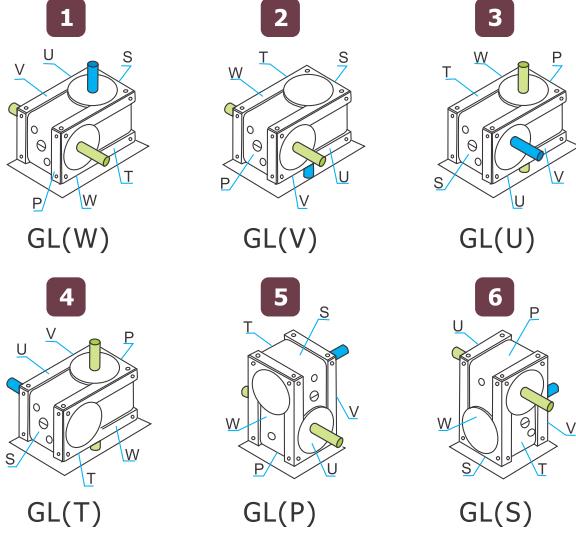

Contact our sales staff for assistance in selecting the most appropriate model for your needs.

Ordering Procedure

- Indexer mounting position: there are six faces available for mounting, V. W. P. S. T. and U. Please specify which face to be mounted on according to the application.
- The model code indicates the positions of the input shaft, the output shaft and the mounting.
- Please specify the model code of the indexing drives needed when placing the order. There are criteria for choosing the correct cam (right rotating or left rotating); as well as choice criteria for the 3 motion curves (MT, MS and MCV50).

DS Series

45DS / 60DS / 70DS / 80DS / 83DS / 100DS
110DS / 125DS / 140DS / 180DS

Product Features

This series of models feature the traditional shaft style. They are installed with some accessories like gears, couplings or clutches. Particular attention should be paid on the diameter tolerances (+0.015 / -0). They are used mostly in belt conveyor drives, gear drives and gap coupling combination drives.

DF Series

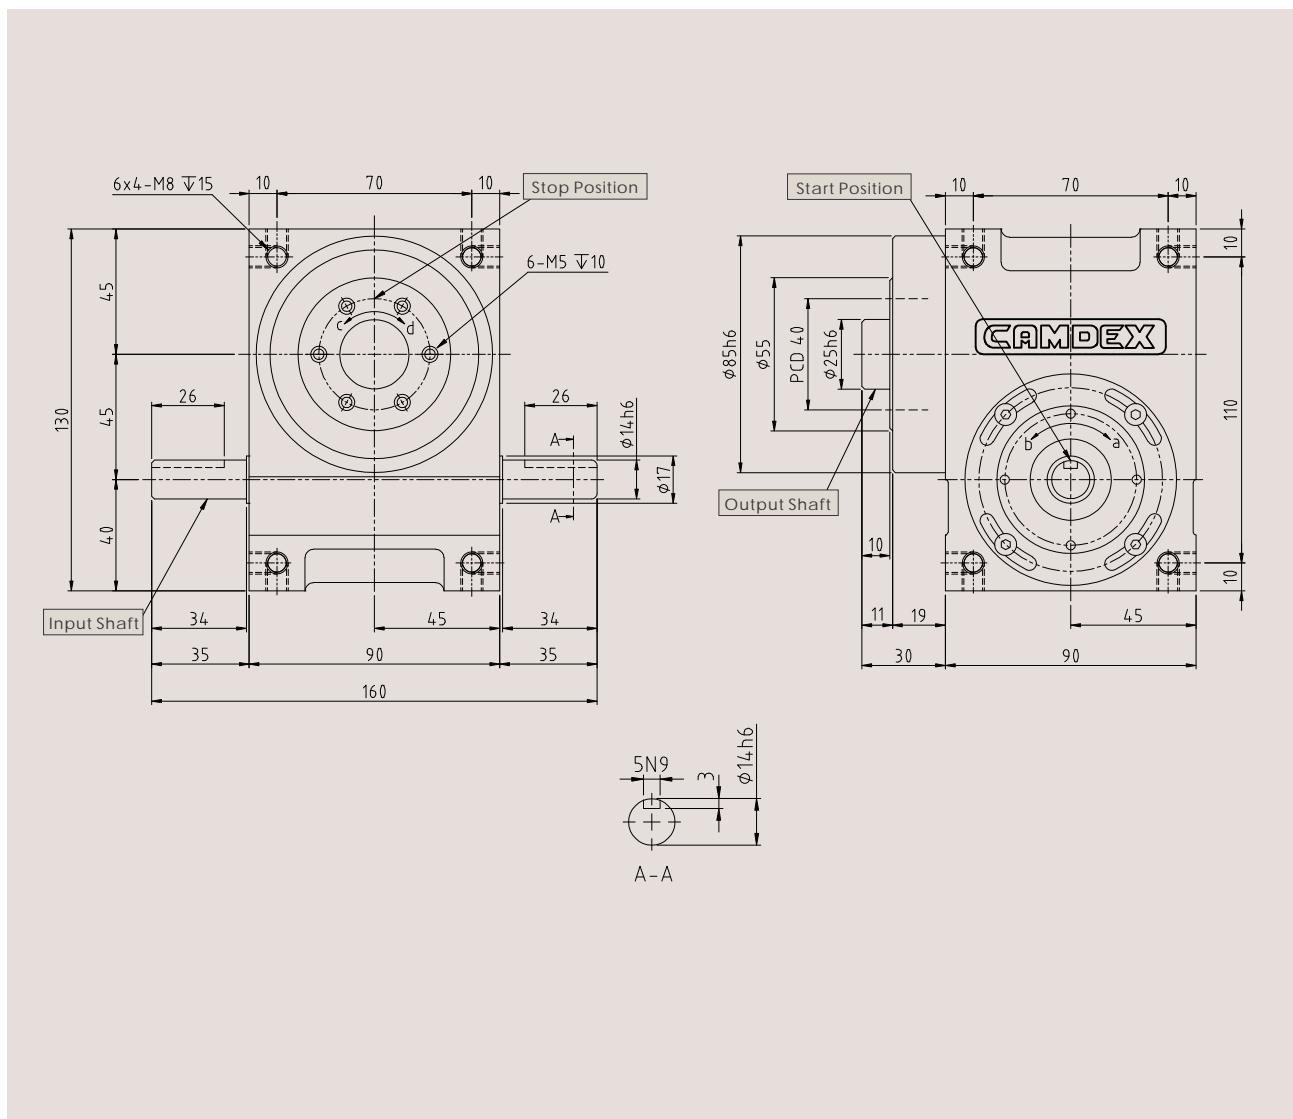

45DF / 60DF / 70DF / 80DF
110DF / 125DF / 140DF / 180DF

Product Features

This series of models are designed for heavy load capacity. They can support higher vertical, radial or axial pressure. The output shaft is disk type, with flange center, disk bolt holes and positioning pin holes. It has larger mounting area, which enhances the flatness and stability and further stabilizes the operation. It is mostly applied to the drives with larger load turn tables. This series of models are widely used in all kinds of turn table processing machines and similar application machines, auto indexing drive units and drive discs.

The output shaft of this series can be made into a hollow flange type, DFH, where H means the output shaft is hollow. The hollow output shaft is to allow wiring, hydraulics, compressed air lines, etc to pass through the center. The hollow shaft's inside diameter and application should be specified in the order.

DA Series

90DA / 110DA / 150DA

Product Features

This series of models have similar size and functional features to DT series. The indexing shaft has a very high axial and radial load capacity. There is a fixed mounting flange at the center of the output shaft for installation of both static and moving automation accessories. The hollow output shaft is to allow wiring, hydraulics, compressed air lines, etc to pass through the center. As a synchronous auto index drive, it is designed to work with other dynamic or static auto machines, for heavy load applications.

WORKING EXAMPLES AND CALCULATIONS

Working Examples and Calculations -1

Features of Curves

Velocity(V_m), Acceleration (A_m) and Input torque (Q_m) of a cam curve have a big influence in the accuracy and lifespan of the indexing drives. It is very important to select the proper cam curve.

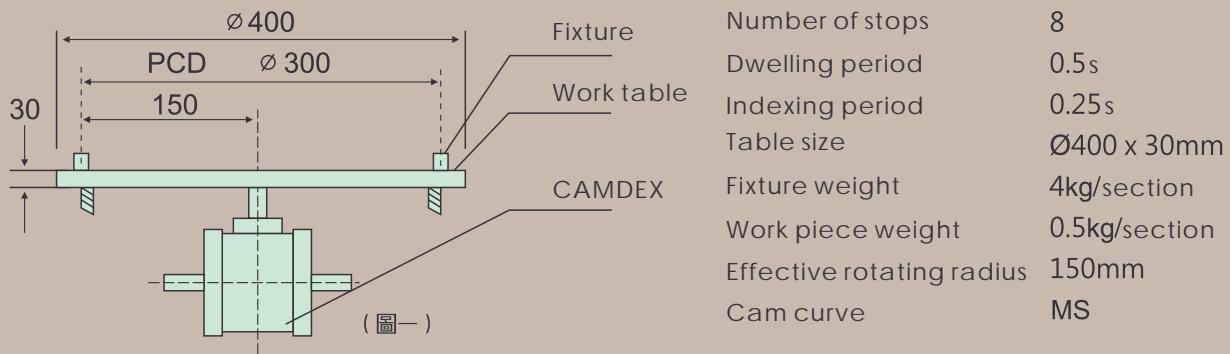

Generally speaking, common curves include Modified Sine Curve (MS), Modified Trapezoid Curve (MT), and Modified Constant Velocity Curve (MV). Principles of selection are shown on the right:

- ① Constant speed (including start and stop)
- ② Constant acceleration (including start and stop)
- ③ The maximums of A_m , V_m and Q_m should be as small as possible
- ④ Select MS, MT with small A_m and big V_m for high speed and light load application
- ⑤ Select MS, MCV with big A_m and small V_m for low speed and heavy load application
- ⑥ Select MS, when speed and load is not sure

Working Example and Calculation

Example 1: for indexing drives for indexing work tableCalculation:

To select indexing drives and matching motors of proper size and specification, the following calculations are performed.

Calculation:

1~1 Number of stops: $S=8$

$$1~2 \text{ Rotating angle } \theta = 360^\circ \times \frac{0.25}{0.25+0.5} = 360^\circ \times \frac{1}{3} = 120^\circ$$

$$1~3 \text{ RPM of input shaft } N = \frac{60}{t_2} \times \frac{\theta}{360} = \frac{60}{0.25} \times \frac{120}{360} = 80\text{rpm}$$

1~4 Cam Curve: Modified Sine Curve, therefore $V_m=1.76$, $A_m=5.53$ $Q_m=0.987$

1~5 Safety Factor for load: $f_e=1.8$

1~6 Friction coefficient $\mu = 0.2$

WORKING EXAMPLES AND CALCULATIONS

Working Examples and Calculations - 1

(1) Ti: Inertia Torque

(a) Table Weight W_1 , Fixture Weight W_2 , Workpiece W_3 , Hence...

$$W_1 = \pi \times 20^2 \times 3 \times 7.85 \times \frac{1}{1000} = 29.59 \text{ kg}$$

$$W_2 = 4 \times 8 = 32 \text{ kg}$$

$$W_3 = 0.5 \times 8 = 4 \text{ kg}$$

(b) Inertia torque of rotating table : I_1 , Inertia torque of fixture : I_2 , Inertia torque of workpiece : I_3 , they are

$$I_1 = \frac{W_1 R_1^2}{2G} = \frac{29.59 \times 0.2^2}{2 \times 9.8} = 0.060 \text{ kgf} \cdot \text{m} \cdot \text{s}^2$$

$$I_2 = \frac{W_2 R_2^2}{G} = \frac{32 \times 0.15^2}{9.8} = 0.0735 \text{ kgf} \cdot \text{m} \cdot \text{s}^2$$

$$I_3 = \frac{W_3 R_3^2}{G} = \frac{4 \times 0.15^2}{9.8} = 0.0092 \text{ kgf} \cdot \text{m} \cdot \text{s}^2$$

(c) Inertia torque total : I

$$I = I_1 + I_2 + I_3 = 0.060 + 0.0735 + 0.0092 = 0.1427 \text{ kgf} \cdot \text{m} \cdot \text{s}^2$$

as it is single flighted $m = 1$

$$\begin{aligned} Ti &= 226.2Am \times \frac{I \cdot N^2}{S(\Theta/m)^2} \\ &= 226.2 \times 5.53 \times \frac{0.1427 \times 80^2}{8 \times 120^2} \\ &= 9.916 \text{ kgf} \cdot \text{m} \end{aligned}$$

(2) Tf: Torque of Friction

$$Tf = \mu \cdot W \cdot R = 0.2 \times (29.59 + 32 + 4) \times 0.15 = 1.968 \text{ kgf} \cdot \text{m}$$

(3) Tw: Working Torque

$$Tw = 0$$

(4) Tt: Total Torque needed

$$Tt = Ti + Tf + Tw = 9.916 + 1.968 + 0 = 11.884 \text{ kgf} \cdot \text{m}$$

Actual loaded torque

$$Te = Tt \cdot fe = 11.884 \times 1.8 = 21.391 \text{ kgf} \cdot \text{m}$$

input shaft torque Tc , Note: the starting loaded torque is considered 0, hence $Tca = 0$

$$Tc = \frac{360}{\Theta \cdot S} \times Qm \times Te = \frac{360}{120 \times 8} \times 0.987 \times 21.391 = 7.917 \text{ kgf} \cdot \text{m}$$

Figure out the power needed, assuming that the motor efficiency is 60%.

$$\begin{aligned} P &= \frac{Tc \times N \times 9.8}{9550 \times 0.6} \\ &= \frac{7.917 \times 80 \times 9.8}{9550 \times 0.6} = 1.083 \text{ kw} \end{aligned}$$

In fact, the calculated result is the maximum starting power, and the normal working power is: $Pa = P \times \frac{1}{2} = 1.083 \times \frac{1}{2} = 0.542 \text{ kw}$

(5) Selecting a proper indexing drive

According to the calculated results and the rotating speed of the input shaft 80RPM, we find from the user manual that indexing drives with output shaft torque greater than Te can be used. As $Te = Te = 21.391 \text{ kgf} \cdot \text{m}$, Ru-110DF should be selected.

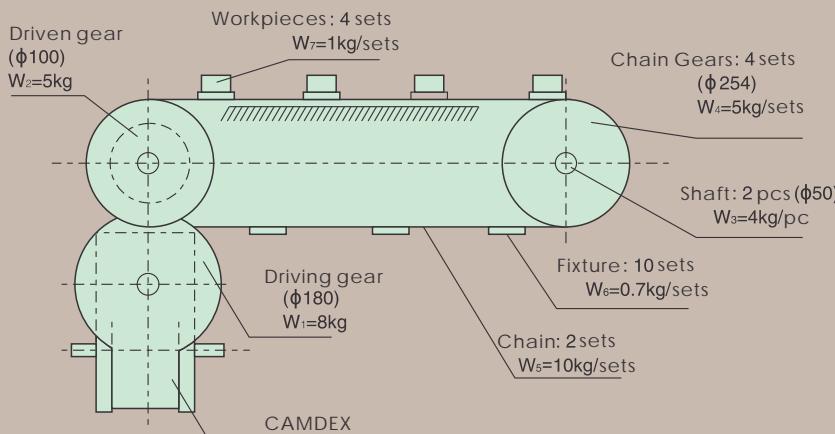

WORKING EXAMPLES AND CALCULATIONS

Working Examples and Calculations -2

Working Example and Calculation

Example 2: indexing drives for conveyor application Indexing drives, with proper gear box for output shaft, can be used in conveyors The relevant calculation of driving the conveyor is as follows:

Designing data and information:
 Convey distance : 239mm
 Rotating angle : $\theta = 120^\circ$
 Operation time per conveyance: 2 seconds/cycle
 Speed ratio $r = \frac{180}{100} = \frac{n}{m}$
 Cam curve: Modified Sine Curve (MS)
 Friction coefficient $\mu = 0.2$
 D_c = Diameter of conveyor gear pitches
 P_c = Horizontal Pitch of Conveyor
 r = Speed ratio

Calculation

2~1 Number of stops : N

$$S = \frac{\pi \times D_c \times r}{P_c} = \frac{\pi \times 25.4 \times 1.8}{23.9} = 6$$

2~2 RPM of input shaft at 2 second/cycle

$$N = \frac{60}{2} = 30 \text{ rpm}$$

2~3 Cam curve: Modified Sine Curve, hence

$$V_m = 1.76, A_m = 5.53, Q_m = 0.987$$

2~4 Loaded Torque : T_f

1: Static Torque (Inertia Torque) : T_i

(a) Weight of the driving gear : W₁=8kg, diameter =φ180

Inertia torque of the driving gear : I_A

$$I_A = \frac{W_1 R^2}{2G} = \frac{8 \times 9^2}{2 \times 980} = 0.331(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

(b) Inertia torque of the conveyor:

① Inertia torque of the driven gear : I₂

$$I_2 = \frac{W_2 (R^2 + r^2)}{2G} = \frac{5(5^2 + 2.5^2)}{2 \times 980} = 0.08(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

② Inertia torque of the transmission shaft : I₃

$$I_3 = \frac{W_3 r^2}{2G} = \frac{4 \times 2.5^2}{2 \times 980} \times 2 = 0.026(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

③ Inertia torque of the chained gears : I₄

$$I_4 = \frac{W_4 (R_e^2 + r^2)}{2G} = \frac{5 \times (12.7^2 + 2.5^2)}{2 \times 980} \times 4 = 1.71(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

④ Inertia torque of the chains : I₅

$$I_5 = \frac{W_5 R_e^2}{G} = \frac{10 \times 12.7^2}{980} \times 2 = 3.29(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

⑤ Inertia torque of the fixtures : I₆

$$I_6 = \frac{W_6 R_e^2}{G} = \frac{0.7 \times 12.7^2}{980} \times 10 = 1.15(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

WORKING EXAMPLES AND CALCULATIONS

Working Examples and Calculations -2

⑥ Inertia torque of the workpieces : I_7

$$I_7 = \frac{W_7 R_e^2}{G} = \frac{1 \times 12.7^2}{980} \times 4 = 0.658(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

⑦ Total inertia torque of the conveyor : I_B

$$I_B = I_2 + I_3 + I_4 + I_5 + I_6 + I_7 \\ = 0.08 + 0.026 + 1.71 + 3.29 + 1.15 + 0.658 = 6.914(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

(c) Effective inertia torque of the conveyor : I_{Be}

$$I_{Be} = I_B \left(\frac{n}{m} \right)^2 = 6.914 \times \left(\frac{180}{100} \right)^2 = 22.4(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

(d) Total torque (a)+(c)之和

$$I = I_A + I_{Be} = 0.331 + 22.4 = 22.731(\text{kg} \cdot \text{cm} \cdot \text{s}^2)$$

(e) Angle Acceleration maximum of the input shaft : α

$$\alpha = Am \frac{2\pi}{S} \left(\frac{360}{\theta} \times \frac{N}{60} \right)^2 = 5.53 \times \frac{2\pi}{6} \left(\frac{360}{120} \times \frac{30}{60} \right)^2 = 13.03(\text{rad} \cdot \text{s}^2)$$

(f) Static torque (Inertia torque)

$$Ti = I \cdot \alpha = 22.731 \times 13.03 = 296.18(\text{kg} \cdot \text{cm})$$

2~5 Friction torque : T_f

(a) Friction torque on the conveyor: the friction load should equal the friction caused by half of the weight of the chains and fixtures on the working surface and total weight of the workpieces.

$$T_f = \mu \cdot W \cdot R = 0.2 \times \left(4 + \frac{0.7 \times 10 + 10 \times 2}{2} \right) \times 12.7 \\ = 44.45(\text{kg} \cdot \text{cm})$$

(b) Effective friction torque of the conveyor : T_{fe}

$$T_{fe} = T_f \left(\frac{n}{m} \right) = 44.45 \times \frac{180}{100} = 80(\text{kg} \cdot \text{cm})$$

2~6 Inertia torque of the workpieces : T_w

$$T_w = 0$$

2~7 Loaded torque : T_t

$$T_t = T_i + T_{fe} + T_w = 296.18 + 80 + 0 = 376.18(\text{kg} \cdot \text{cm}) = 3.76(\text{kg} \cdot \text{m})$$

2~8 Actual loaded torque : T_e , Loaded safety factor $f_e = 2$

$$T_e = T_f \cdot f_e = 3.76 \times 2 = 7.52$$

2~9 Input shaft torque : T_c

$$T_c = \frac{360}{S} \cdot \frac{1}{\theta} \cdot Q_m \cdot T_e + T_{ca} = 0$$

Note: The Starting loaded torque of the input shaft is 0, hence $T_{ca} = 0$

$$T_c = \frac{360}{6} \times \frac{1}{120} \times 0.987 \times 7.52 + 0 = 3.71$$

2~10 Figure out the power needed : P

assuming that the motor efficiency is $\eta = 60\%$

$$P = \frac{T_c \times N}{975 \times \eta} (\text{kw}) \\ \frac{3.71 \times 30}{975 \times 0.6} = 0.19(\text{kw})$$

the calculated result is the maximum starting power, and the normal working power is 1/2 of the starting power.

$$0.19 \times \frac{1}{2} = 0.095\text{kw}$$

2~11 Selecting a proper indexing drive

According to the calculated results, the rotating speed of the input shaft 30RPM, the torques reference chart in this catalogue and other relevant information, RU70DS should be selected.

P225 / P250 / P320

Product Features

Product Features: It contains two plate type cams and the turret driven by the cam followers. This index drive has parallel co-shaft cams, whose rotation drives the cam follower turret to perform indexing. It is most suitable for driving large pitch distance conveyor or for longer dwell indexing. 3-parallel cam type is available for heavier load capacity, suitable for longer pitch distance transportation at a higher speed. The dwell period is also longer than that of 2-parallel cam type.

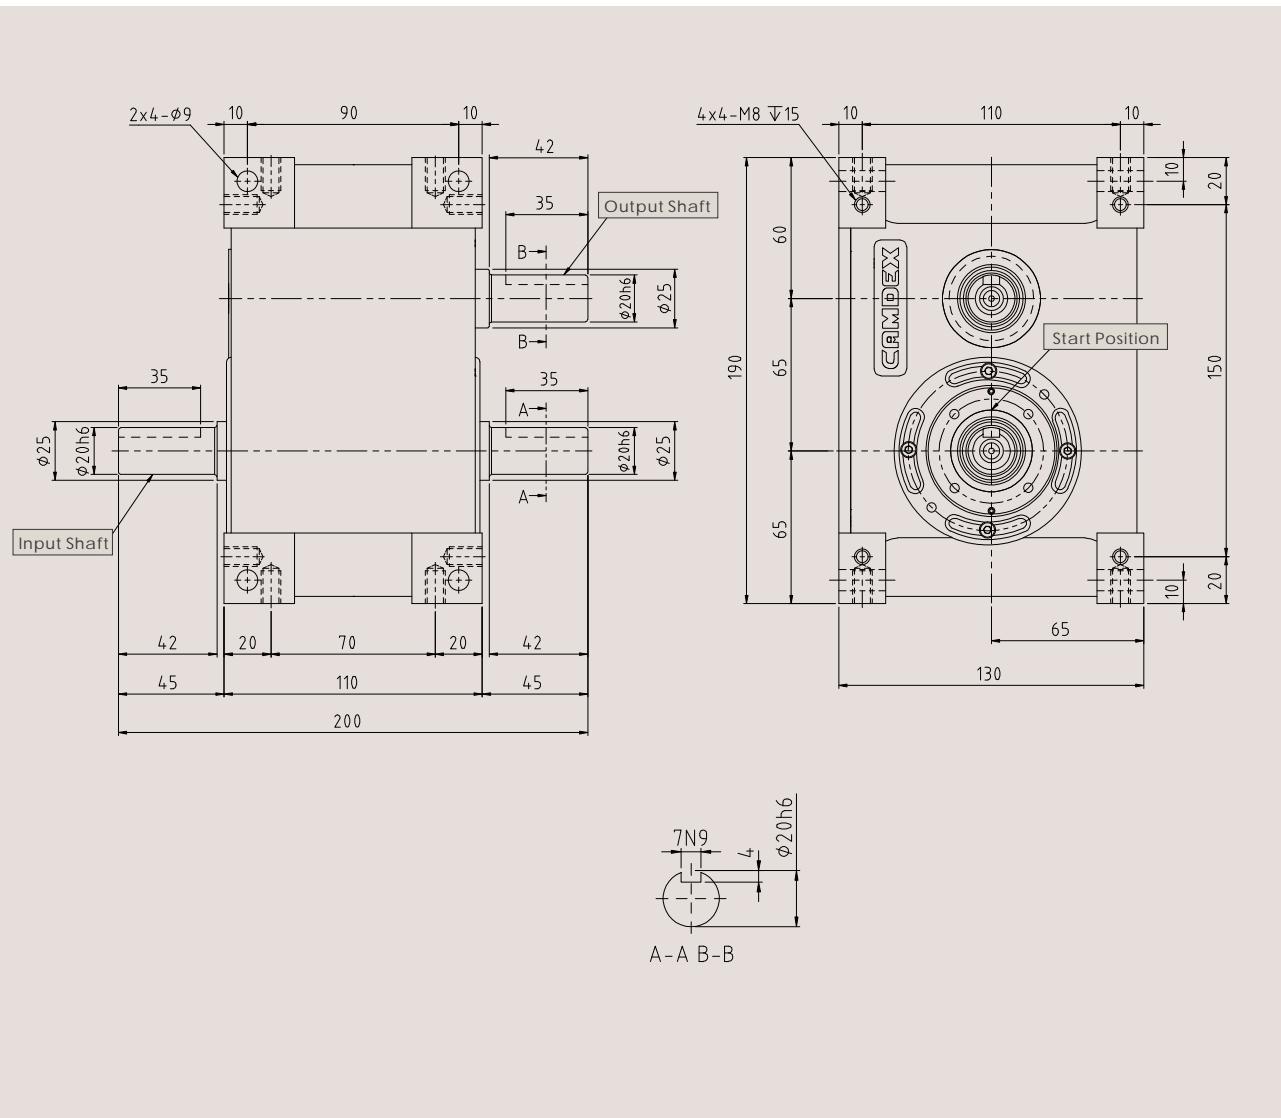

Model Code Designation:

A Machine Type	B Specification	C Type	D No. of Stop (S)	E Indexing Angle (θ h)	F Motion Curve		G Cam Rotation Direction		
P Parallel	100D 100mm	S Type	01 1 stop	270 270 °	2	MS Curve	A	Counter-Clockwise

Note:

The reference value of the safe load F_e is:

When the indexing angle is 90° , the safety factor = load torque (T_t) X2.22 (times)

When the indexing angle is 120° or above, the safety factor = load torque (T_t) x2.0 (times)

Note: For safety factor calculation, when the input shaft speed is lower than 35rpm, it will be considered as 35rpm.
